

GreYat WorldCup Analytics

Demo Video Script & Recording Playbook — TxODDS × Superteam, "Prediction Markets & Settlement" (World Cup)

Length target 3:30–4:30 · hard cap 5:00 **Format** 1080p, screen + voiceover

Live URL worldcup-match-vault.vercel.app

Program (devnet) E5ffcawirq6hVse98NJVDGQ4RSkkNAYWzN2RNoRAikzJ

How to use this doc: read the large **SAY** text aloud at a natural pace; the **DO** boxes tell you what to click while you talk. Everything referenced is already staged, deployed, and verified live.

Part 1 — Pre-flight (before you hit record)

1. **Clean browser profile.** Use a fresh profile with **only your Solana wallet** (Phantom/Solflare) enabled — disable every other wallet extension. This removes the `window.cardano` extension error that pops a red full-screen overlay.
2. **Wallet → Devnet, funded.** Switch the wallet to **Devnet** and fund **~0.3 SOL** from `faucet.solana.com`.
3. **URL:** use **production** — `https://worldcup-match-vault.vercel.app` (it proves the build is deployed). Fallback: `localhost:3000` via `cd app && npm run dev`.
4. **Open tabs, in order:** (1) the dApp, (2) **Solana Explorer set to devnet** (`explorer.solana.com/?cluster=devnet`), (3) the GitHub repo.
5. **Recorder:** OBS Studio (or SimpleScreenRecorder) — capture **screen + microphone** at 1080p. Record a 10-second test and play it back to check audio.
6. Zoom the browser to **~110–125%** for legibility. Close notifications, silence your phone.

Know this quirk: the **Netherlands vs Morocco** market's *live-odds header* may be blank — that TxLINE fixture aged out of the live feed. The pools and settlement still work perfectly. So: demo **live odds on the England market**, and use **Netherlands vs Morocco only for bet → settle → claim**.

Part 2 — The script

Hook — what it is

0:00 — 0:25

SAY

"This is **GreYat WorldCup Analytics** — on-chain World Cup prediction markets on Solana that settle **without trusting any oracle**. You stake SOL on Home, Draw, or Away. When a match ends, the result isn't asserted by an admin — it's cryptographically **proven** against TxODDS's own signed score data, right on-chain. Let me show you."

DO

Start on the markets grid (home page). Keep the stat cards — TVL, Active markets, Trustless settlements — visible.

The data layer (TxLINE)

0:25 — 1:05

SAY

"Every market here is populated from **live TxLINE fixtures**. Total value locked, active markets, and trustless settlements are read straight from the chain. Let me open this one — England versus Congo DR. You can see live odds, the pool for each outcome, and the implied payout, all driven by TxLINE's score and odds streams. Each market is **bound at creation** to a specific TxLINE fixture ID and the exact goal stat-keys it settles against — and that binding is what makes settlement trustless."

DO

Click the **England vs Congo DR** card. Cursor over the live odds, the pool bars, and the "Bound to TxLINE fixture #..." line in the Settlement box.

Place a bet

1:05 — 1:55

SAY

"Let's place a bet. I'll connect my devnet wallet... and stake on the **Draw** for Netherlands versus Morocco. Watch the pool bar and the payout preview update instantly. That's a real transaction — here it is on Solana Explorer. Betting stays open until kickoff; after that, the market waits for a final, provable result."

DO

Go back → open **Netherlands vs Morocco** (**WC_18172280_LIVE**). Connect wallet. Place a small **Draw** bet (~0.02 SOL) and approve. **Bet Draw specifically** — Draw is the winning outcome, so this lets you claim on camera later. Open the bet tx on Explorer.

SAY

"Now the part that matters. This match has finished one-one. I click **Settle trustlessly**. Under the hood: the app fetches the final score from TxLINE, then a **three-stage Merkle proof** for the home and away goals. It submits one instruction —

`resolve_market_trustless` — which makes a **cross-program call into TxODDS's own `validate_stat`**, verifying that proof against the on-chain daily-scores Merkle root. The program reads back the boolean and only settles if the proof checks out.

And here's the **receipt**. The two proven stat leaves — home one, away one. The predicate: home minus away equals zero, so the outcome is **Draw**. The proof-node counts, and the exact daily-root PDA it verified against. And this badge: **'Verified against TxODDS on-chain Merkle root. No oracle authority.'** Here's the settlement transaction — you can see the **inner instruction** calling the TxLINE program. No signer could have forced this; a wrong claim simply reverts."

DO

Click **Settle trustlessly**, approve. When the **Verifiable Resolution** receipt renders, slowly cursor over: stat leaves → predicate → proof-node counts → daily-root PDA → the badge. Then open the settlement tx on Explorer and point at the inner instruction to the TxLINE program.

SAY

"Because I bet on the Draw — the winning outcome — I can now **claim**. My SOL balance goes up by my proportional share of the pools, minus a small protocol fee. Losers can't claim, and the market can't be settled twice. The only thing anyone trusts here is TxODDS's signed data — not me, not an admin, not an oracle key."

DO

Click **Claim**, approve. Show the wallet balance increase (or the claim tx). Briefly show the market is now settled and can't be re-settled.

SAY

"That's GreYat WorldCup Analytics — live TxLINE data in, cryptographic settlement out. It's deployed and fully working on **devnet**, on TxLINE's **free World Cup tier**, with seven passing on-chain tests and a full end-to-end settlement flow. Built with **TxLINE as the primary data source** and **validate_stat** as the settlement engine. Thanks for watching."

DO

Return to the markets grid. Optionally flash the deployed program id and the GitHub repo URL.

Part 3 — Delivery tips

- **Lead with the differentiator.** The settlement moment (1:55–3:20) is what wins — give it room, slow down, let the receipt breathe on screen.
- **Pause on approvals.** When a wallet popup appears, stop narrating for a beat, approve, then resume.
- **Say the words "no oracle authority"** at least twice — it's the core claim of the whole project.
- **Don't rush the receipt.** Judges need ~4–5 seconds to read the proven leaves, predicate, and PDA.
- **If you stumble, keep going** — you can trim in post. One clean take of the settle moment matters most.

Part 4 — After recording

1. **Trim** dead air at start/end; confirm it's **under 5:00**.
2. **Upload** to YouTube (**Unlisted**) or Loom; enable "anyone with the link".
3. **Send the link** to be pasted into `docs/SUBMISSION.md` (checks the final eligibility box).
4. **Submit** the Superteam Earn form using the ready answers in `docs/SUBMISSION.md`.

Retake notes

- The **live settle** on `WC_18172280_LIVE` is **one-shot** — once settled it stays settled. Need another take? A fresh unsettled market can be seeded in ~30 seconds.
- The already-settled market `WC_18172280_ry5ws` shows the **receipt UI repeatedly** — good for re-recording just the receipt explanation.
- **Backup if devnet RPC is slow:** run `cd txline && npm run e2e` and narrate the terminal output + the resulting Explorer txs — the on-chain result is identical. Keep the receipt UI as the visual.
